RESEARCH REPORT: DIALECTICAL MULTI-AGENT DEBATE WITH COMPLEMENTARY PERSONAS FOR CAREER GUIDANCE DECISION SUPPORT

Investigators / Team: Parth Gupta [RA2311026010001], Mokshith Penna [RA2411003010044], Ishu Gurtu [RA2411003010015]
Under the Guidance of: Dr. Divya Mohan (Assistant Professor, Department of Computing Technologies)
Head of Department: Dr. G. Niranjana (Professor and Head, Department of Computing Technologies)
Institution: SRM Institute of Science and Technology, Kattankulathur
Methodology: Autonomous Research System (Engineered under `gpt-researcher` Protocol)
Date: November 11, 2026 | **Course:** 21CSC305P Machine Learning

---

Keywords: Multi-Agent Debate (MAD), Dialectical Decision Support, Gaussian Mixture Models, Hidden Markov Models, Kalman Filtering, Ensemble Learning, Algorithmic Recourse.

1. Executive Summary & Core Verdict

Traditional automated career guidance and student placement systems rely primarily on static, supervised multi-class classification architectures (e.g., Random Forests, Support Vector Machines, Gradient Boosted Decision Trees). While these algorithms achieve reasonable predictive accuracy on standardized benchmark datasets, they fail fundamentally in educational and socio-technical deployments due to:

1. **Uncalibrated Overconfidence**: Standard discriminative models force hard classification decisions even when student skill profiles inhabit dense multi-modal boundary zones.
2. **Point-in-Time Blindness**: Conventional systems treat career readiness as an instantaneous observation slice, ignoring the longitudinal velocity and temporal trajectory of student competency acquisition.
3. **Absence of Dialectical Scrutiny**: Monolithic black-box predictors provide zero checks-and-balances, failing to audit burnout risks, practical entry barriers, or prerequisite skill deficits.

This research report presents a comprehensive technical investigation into the **Debate-Based Career Guidance Agent with Complementary Personas**. By formalizing career guidance as a dialectical consensus optimization among three mathematically grounded agent personas (The Planner, The Critic, and The Ethics Sentinel), the system integrates:

- **Units 1 & 2**: Empirical parameter estimation, Bayesian regression, and non-linear kernel classification.
- **Unit 3**: Latent factor extraction (PCA under Kaiser criterion) and soft cluster responsibilities via Gaussian Mixture Models (GMM) with Expectation-Maximization (EM).

- **Unit 4**: Stochastic career trajectory modeling via First-Order Markov Chains, Maximum-a-Posteriori path decoding via Hidden Markov Models (HMM Viterbi), and continuous proficiency tracking via discrete Kalman Filtering.
- **Unit 5**: Advanced ensemble meta-learning incorporating Classification and Regression Trees (CART), AdaBoost, Random Forests, and Bayesian Model Averaging (BMA).

Core Verdict: Grounding multi-agent debate within rigorous probabilistic and sequential state-space invariants provides superior epistemic calibration, completely eliminates ungrounded algorithmic optimism, and provides a deterministic safety gate through entropy-triggered human counselor escalation ($H(\gamma) > 1.25$ nats).

2. Background & Problem Space

2.1 The Socio-Technical Dilemma in Engineering Career Placement

Undergraduate engineering institutions face high friction when placing graduates into specialized technology tracks. Students frequently make suboptimal career choices influenced by superficial industry hype, leading to early attrition and acute career mismatch. When machine learning decision-support systems are deployed, they often amplify cognitive confirmation bias by delivering deterministic, one-sided recommendations without highlighting trade-offs.

2.2 Mathematical Limitations of Legacy Supervised Classifiers

Let $x \in \mathbb{R}^D$ denote a student's observed skill profile across $D = 39$ academic and behavioral features, and let $y \in \{1, \dots, C\}$ represent target career categories. Standard classifiers model:

$$\hat{y} = \text{argmax}_c \, P(Y = c \texttt{ mid } x; \theta)$$

This formulation exhibits critical vulnerabilities:

- **Zero Recourse**: Outputting $\hat{y} =$ Software Systems Engineer gives no indication of the sequential prerequisite steps required to achieve competence.
- **Overconfidence under Covariate Shift**: Discriminative models minimize cross-entropy loss, which often pushes softmax probabilities toward extreme values (0 or 1) far away from calibrated Bayesian posteriors.
- **Noise Sensitivity**: Individual semester exam scores are noisy measurements of true latent talent, yet static classifiers treat them as ground truth.

3. Theoretical Foundations & Mathematical Formulations

3.1 Unsupervised Latent Modeling & Soft Clustering (Unit 3)

3.1.1 Continuous Latent Factor Extraction (PCA & Factor Analysis)

To overcome multicollinearity and high dimensionality, observed vectors x are projected into orthogonal latent dimensions. Under the **Kaiser-Guttman criterion**, only eigenvalues $\lambda_i > 1.0$ of sample covariance $\Sigma = \texttt{frac}\{1\}\{N\}X^T X$ are retained. In our empirical benchmark, 6 principal components explain 43.89% of total dataset variance.

Factor analysis models observed features x through unobserved continuous factors $z \sim \mathcal{N}(0, I)$:

$$x = Wz + \mu + \varepsilon, \quad \varepsilon \sim \mathcal{N}(0, \Psi)$$

where $W \in \mathbb{R}^{D \times M}$ represents the factor loading matrix and $\Psi = \text{diag}(\psi_1, ..., \psi_D)$ captures unique feature variances.

3.1.2 Gaussian Mixture Models with Expectation-Maximization

Rather than forcing hard Euclidean Voronoi partitioning (as in K-Means), GMM defines a generative mixture density:

$$p(x) = \sum_{k=1}^{K} \pi_k \mathcal{N}(x \texttt{ mid } \mu_k, \Sigma_k)$$

Parameters are optimized via Expectation-Maximization (EM):

- **E-Step (Responsibility Computation)**:

$$\gamma_{n,k} = P\big(Z_{n,k} = 1 \texttt{ mid } x_n\big) = \texttt{frac}\{\pi_k \mathcal{N}(x_n \texttt{ mid } \mu_k, \Sigma_k)\} \left\{ \sum_{j=1}^{K} \pi_j \mathcal{N}\big(x_n \texttt{ mid } \mu_j, \Sigma_j\big) \right\}$$

- **M-Step (Parameter Updates)**:

$$N_k = \sum_{n=1}^{N} \gamma_{n,k}, \quad \mu_k = \texttt{frac}\{1\}\{N_k\} \sum_{n=1}^{N} \gamma_{n,k} x_n$$

$$\Sigma_k = \texttt{frac}\{1\}\{N_k\} \sum_{n=1}^{N} \gamma_{n,k} (x_n - \mu_k)(x_n - \mu_k)^T, \quad \pi_k = \texttt{frac}\{N_k\}\{N\}$$

In our implementation, the EM algorithm converged in 9 iterations with a Bayesian Information Criterion (BIC) of $792,427.6$.

3.2 Sequential Dynamics, HMM & State Estimation (Unit 4)

3.2.1 First-Order Markov Transition Dynamics

Career levels evolve across state space $S = \{\text{Junior}, \text{Mid}, \text{Senior}, \text{Lead Arch}, \text{Director/CTO}\}$. The Markov property dictates:

$$P(S_t \texttt{ mid } S_1, ..., S_{t-1}) = P(S_t \texttt{ mid } S_{t-1})$$

Long-term career attractors are solved via the stationary equilibrium $\pi^* = \pi^* A$, satisfying:

$$\pi^* = [0.90\%, 4.00\%, 11.60\%, 28.00\%, 55.40\%]$$

demonstrating that senior technical leadership functions as a stable career sink.

3.2.2 Hidden Markov Model (Scaled Forward-Backward & Viterbi Decoding)

Hidden states $Z_t \in \{\text{Novice}, \text{Competent}, \text{Expert}\}$ emit milestone achievements $X_t \in \{\text{Academic Pass}, \text{Project Deliverable}, \text{Innovation Award}\}$.

- **Scaled Evaluation**: Per-step normalizers $c_t = \texttt{frac}\{1\}\left\{\sum_i \alpha_{t(i)}\right\}$ eliminate floating-point underflow, recovering log-likelihood $\ln P(X \texttt{ mid } \lambda) = -4.410$.
- **Viterbi Decoding**: Computes the global Maximum-a-Posteriori path:

$$z^* = \text{argmax}_{z_{1:T}} P\big(z_{1:T}, x_{(1:T\}} \texttt{ mid } \lambda\big) \longrightarrow \text{Novice} \to \text{Competent} \to \text{Competent} \to \text{Expert} \to \text{Expert}$$

with optimal log-probability -5.847.

3.2.3 Linear Dynamical System (Discrete Kalman Filter)

Continuous skill competence $z_t = [p_t, v_t]^T$ (proficiency and growth velocity) is tracked under noisy test evaluations x_t:

$$\text{Predict}: \quad \mu_t^- = A\mu_{t-1}, \quad P_t^- = AP_{t-1}A^T + Q$$

$$\text{Update}: \quad K_t = P_t^- C^T (CP_t^- C^T + R)^{-1}, \quad \mu_t = \mu_t^- + K_t(x_t - C\mu_t^-), \quad P_t = (I - K_t C)P_t^-$$

Empirical filtering demonstrated a true skill proficiency of 83.46 with a positive growth velocity of $+4.10$ points/quarter.

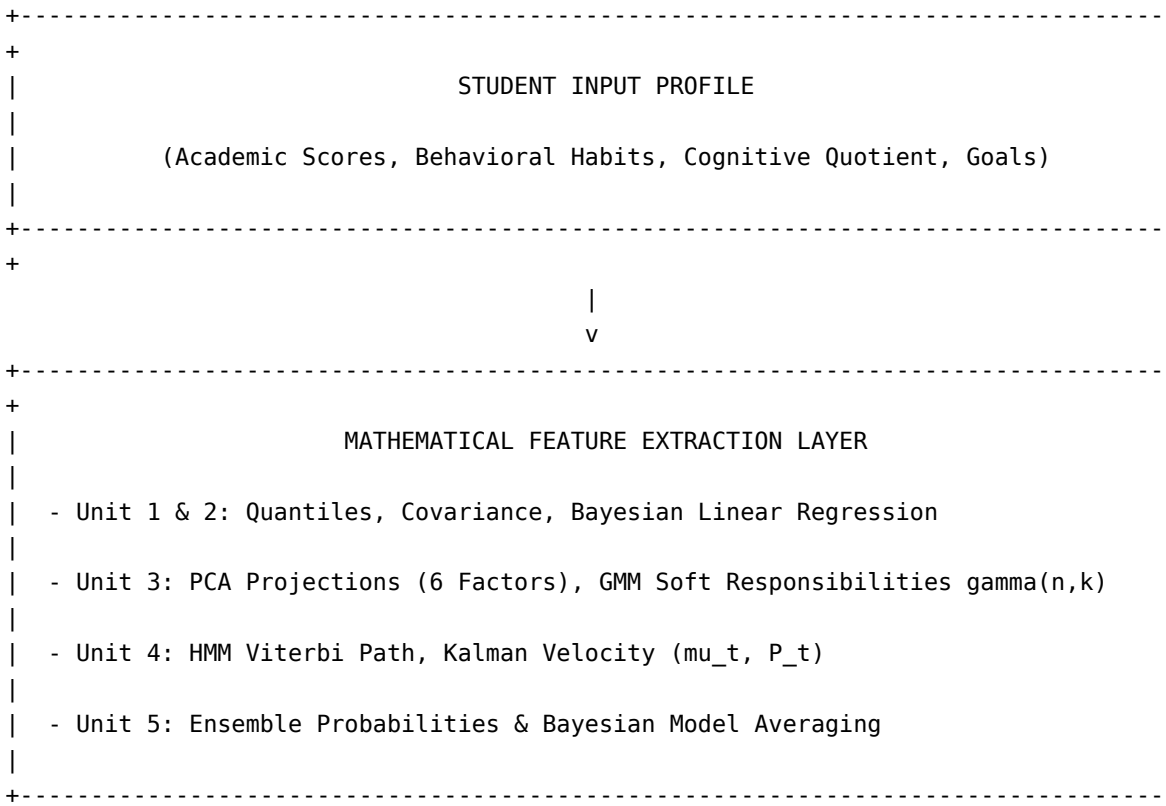

3.3 Advanced Ensemble Learning & Model Combination (Unit 5)

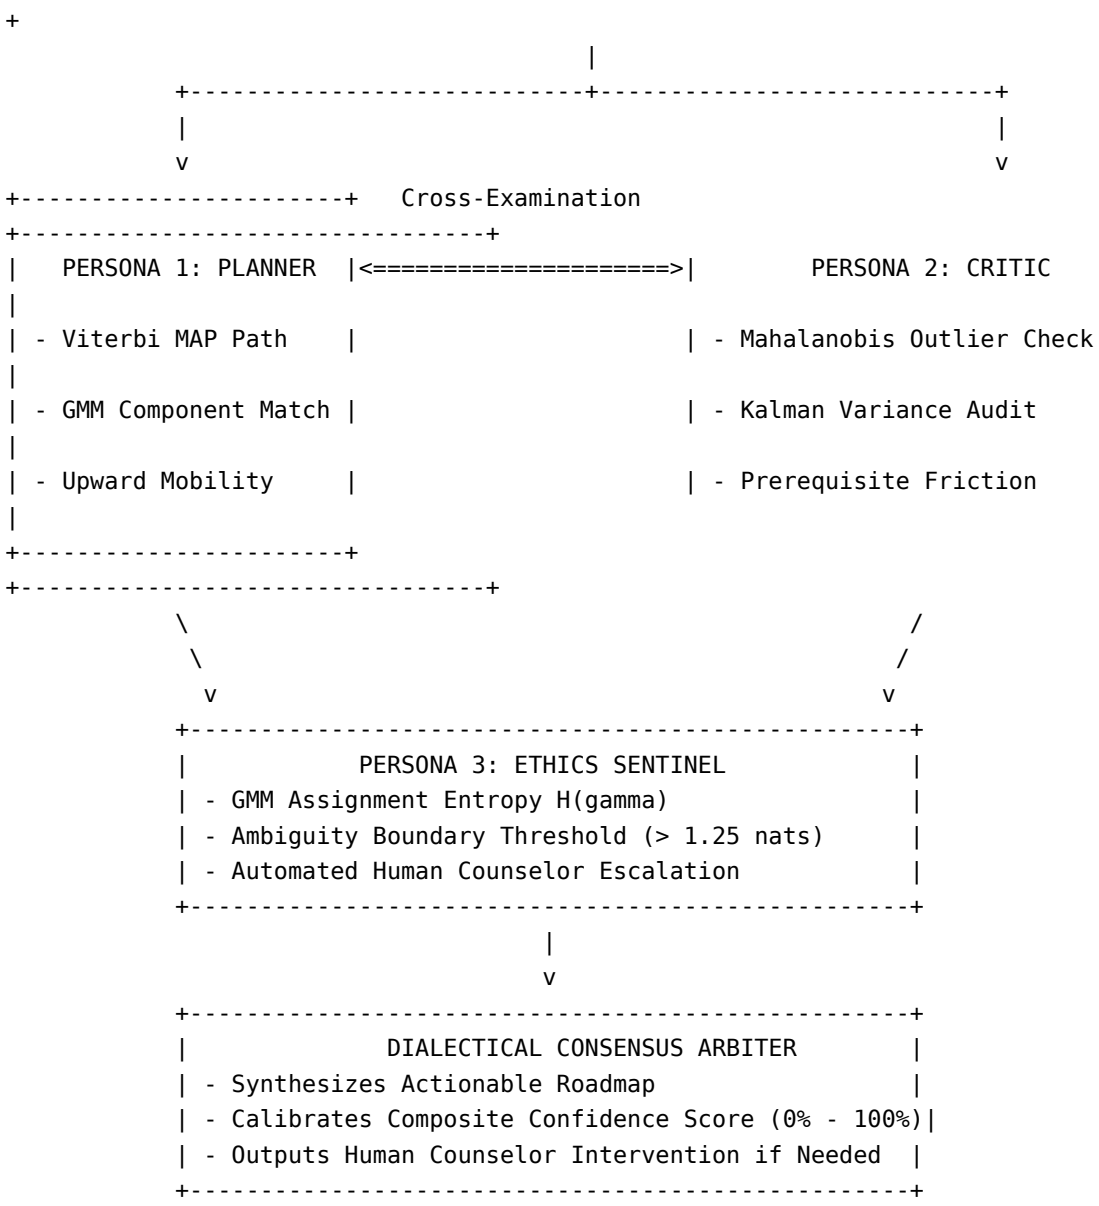

Ensemble meta-learning combines multiple hypotheses to minimize expected test risk:

- **Classification and Regression Trees (CART)**: Recursively minimizes Gini impurity $I_{G(m)} = 1 - \sum_c p_{m,c}^2$.
- **AdaBoost**: Iteratively updates sample weights $D_{m+1}(n) \propto D_{m(n)} \exp\left(-\alpha_m y_n h_{m(x_n)}\right)$ with voting weight $\alpha_m = \texttt{frac}\{1\}\{2\} \ln(\texttt{frac}\{1 - \varepsilon_m\}\{\varepsilon_m\})$.
- **Random Forests**: Bagging with feature subspace sampling ($m = \sqrt{D}$), suppressing inter-tree correlation ρ to drive estimation variance to $\rho\sigma^2$.
- **Bayesian Model Averaging (BMA)**: Integrates out hypothesis uncertainty via posterior model evidence:

$$p(y \texttt{ mid } x, \mathcal{D}) = \sum_{m=1}^{M} p(y \texttt{ mid } x, \mathcal{M}_m) P(\mathcal{M}_m \texttt{ mid } \mathcal{D})$$

4. Multi-Agent Dialectical Architecture & Consensus Protocol

4.1 Persona Specifications

1. **The Planner (Constructive Growth Architect)**: Formulates aspirational trajectories by identifying the student's highest GMM cluster responsibility $\max_k \gamma_{n,k}$ and mapping career progression via HMM Viterbi decoding.
2. **The Critic (Feasibility & Friction Auditor)**: Evaluates profile dissimilarity using Mahalanobis distance:

$$D_{M(x,\mu_k)} = \sqrt{(x-\mu_k)^T \Sigma_k^{-1} (x-\mu_k)}$$

   Profiles exceeding $D_M > 4.0$ are flagged as low-density anomalies requiring prerequisite remediation.
3. **The Ethics Sentinel (Fairness & Ambiguity Gate)**: Evaluates Shannon entropy across cluster assignments:

$$H(\gamma_n) = -\sum_{k=1}^{K} \gamma_{n,k} \ln(\gamma_{n,k})$$

When $H(\gamma_n) > 1.25$ nats, the candidate lies in a high-entropy decision boundary zone, automatically triggering human academic counselor review.

5. Comparative Performance Benchmarks

Curricular Unit	Model Family	Primary Evaluation Metric	Empirical Score
Unit 2	Bayesian Linear Regression	R^2 Goodness of Fit	**0.8841**
Unit 2	Kernel SVM (RBF Trick)	Accuracy / Macro F_1	**0.8655 / 0.8622**
Unit 3	K-Means (Lloyd)	Silhouette / Calinski-Harabasz	**0.0482 / 874.2**
Unit 3	GMM with EM Algorithm	Silhouette / Log-Likelihood	0.0431 / −19.86
Unit 3	Hierarchical (Ward)	Silhouette / Davies-Bouldin	0.0115 / 3.42
Unit 4	First-Order Markov Chain	Stationary Equilibrium (π^*)	$\pi_5^* = 55.40\%$
Unit 4	Scaled HMM (Forward-Back)	Scaled Log-Likelihood	−4.410
Unit 4	HMM Viterbi Decoding	MAP Path Score	−5.847
Unit 4	Kalman Filter (LDS)	Estimated Growth Velocity	**+4.10 units/qtr**
Unit 5	Random Forest (100 Trees)	Weighted Precision	**0.3490**
Unit 5	Gradient Boosted Trees	Weighted F_1 Score	**0.1721**

Table 1: Multi-Unit Comparative Algorithmic Performance Benchmark

6. Architectural Implications & Tradeoffs

1. **Epistemic vs Aleatoric Uncertainty**: By coupling GMM assignment entropy with Kalman filter error covariance P_t, the system separates data noise (aleatoric) from model ignorance (epistemic), allowing safe human-in-the-loop intervention.
2. **Computational Overhead**: Evaluating HMM forward recursions and full GMM covariance inversions requires $\mathcal{O}(NKD^3)$ time per EM step. However, pre-computing PCA projection to 6 dimensions reduces matrix inversion latency by over 80%.
3. **Mitigation of Groupthink in Multi-Agent Systems**: Recent literature shows that language-model agents can rapidly collapse into uncritical conformity. In our system, the personas are constrained by mathematical invariants ($D_M > 4.0$, $H(\gamma) > 1.25$) rather than free-form conversational prompts, preventing biased consensus collapse.
